

Python programming

Operators

OPERATORS

Variables and assignment

We've already used the assignment operator when using variables.

The = symbol is so familiar we hardly notice it.

When a programmer reads this symbol, they probably don't think "equals", more likely they think "is".

```
message = "This is fine"
```

OPERATORS

Arithmetic

Computers are great at arithmetic, so it's no surprise that Python has a simple syntax for arithmetic.

```
2 + 2
```

```
(50 - 5*6) / 4
```

Values can be replaced by variables.

```
width = 12.2
```

```
height = 45.5
```

```
area = width * height
```

OPERATORS

Strings

Joining text strings is easy, although Python doesn't see text in the way we do. These are all the same.

```
"alice"+"bob"
```

```
"alice" "bob"
```

```
("alice"  
 "bob")
```

And none of these are what you might intend!

Try it.

OPERATORS

The less familiar

// # integer division

% # division remainder (modulus)

-= # decrement

+= # increment

** # exponent

OPERATORS

Slicing strings

Sometimes we just want part of a string.

```
name = "alice"  
initial = name[0]  
day = "thursday"  
abbrev = day[0:3]
```

METHODS

Often there is no obvious symbol

```
my_name = "MICHAEL".capitalize()
```

```
str.replace(old, new[, count])
```

Return a copy of the string with all occurrences of substring *old* replaced by *new*. If the optional argument *count* is given, only the first *count* occurrences are replaced.

```
str.rfind(sub[, start[, end]])
```

Return the highest index in the string where substring *sub* is found, such that *sub* is contained within *s[start:end]*. Optional arguments *start* and *end* are interpreted as in slice notation. Return *-1* on failure.

```
str.rindex(sub[, start[, end]])
```

Like *rfind()* but raises *ValueError* when the substring *sub* is not found.

```
str.rjust(width[, fillchar])
```

Return the string right justified in a string of length *width*. Padding is done using the specified *fillchar* (default is an ASCII space). The original string is returned if *width* is less than or equal to *len(s)*.

<https://docs.python.org/3/library/stdtypes.html#string-methods>

FUNCTIONS

Return a result that depends on inputs

```
str_len = len("MICHAEL")  
smaller = min(9,100,4)
```

BUILT IN FUNCTIONS

Frequently used functions are built in to the Python system.

		Built-in Functions		
<code>abs()</code>	<code>delattr()</code>	<code>hash()</code>	<code>memoryview()</code>	<code>set()</code>
<code>all()</code>	<code>dict()</code>	<code>help()</code>	<code>min()</code>	<code>setattr()</code>
<code>any()</code>	<code>dir()</code>	<code>hex()</code>	<code>next()</code>	<code>slice()</code>
<code>ascii()</code>	<code>divmod()</code>	<code>id()</code>	<code>object()</code>	<code>sorted()</code>
<code>bin()</code>	<code>enumerate()</code>	<code>input()</code>	<code>oct()</code>	<code>staticmethod()</code>
<code>bool()</code>	<code>eval()</code>	<code>int()</code>	<code>open()</code>	<code>str()</code>
<code>breakpoint()</code>	<code>exec()</code>	<code>isinstance()</code>	<code>ord()</code>	<code>sum()</code>
<code>bytearray()</code>	<code>filter()</code>	<code>issubclass()</code>	<code>pow()</code>	<code>super()</code>
<code>bytes()</code>	<code>float()</code>	<code>iter()</code>	<code>print()</code>	<code>tuple()</code>
<code>callable()</code>	<code>format()</code>	<code>len()</code>	<code>property()</code>	<code>type()</code>
<code>chr()</code>	<code>frozenset()</code>	<code>list()</code>	<code>range()</code>	<code>vars()</code>
<code>classmethod()</code>	<code>getattr()</code>	<code>locals()</code>	<code>repr()</code>	<code>zip()</code>
<code>compile()</code>	<code>globals()</code>	<code>map()</code>	<code>reversed()</code>	<code>__import__()</code>
<code>complex()</code>	<code>hasattr()</code>	<code>max()</code>	<code>round()</code>
